Abstract

We introduce LaMachine, a unified Natural Language Processing (NLP) open-source software distribution to facilitate the installation and deployment of a large amount of software projects that have been developed in the scope of the CLARIN-NL project and its current successor CLARIAH. Special attention is paid to encouragement of good software development practises and reuse of established infrastructure in the scientific and open-source software development community. We illustrate the usage of LaMachine in an exploratory text mining project at the Dutch Health Inspectorate where LaMachine was applied to create a research environment for automatic text analysis for health care quality monitoring.

1 Introduction

Software is a key deliverable and a vital component for research in projects such as those under the CLARIN umbrella. It is software that provides researchers the instruments to yield for their research; It is CLARIN's core mission to make digital language resources, including software, available to the wider research community.

We see that NLP software often takes on complex forms such as processing pipelines invoking various individual components, which in turn rely on various dependencies. Add dedicated web-interfaces on top of that and you obtain a suite of interconnected software that is often non-trivial to install, configure, and deploy. This is where LaMachine comes in.

LaMachine incorporates software providing different types of interfaces[1] that typically address different audiences. Whilst we attempt to accommodate both technical[2] and less-technical audiences[3], there is a natural bias towards the former as lower-level interfaces are often a prerequisite to build higher-level interfaces on. Depending on the *flavour* of LaMachine chosen, it makes a good virtual research environment for a data scientist, whether on a personal computer or on a computing cluster, a good development environment for a developer or a good deployment method for production servers in for example CLARIN centres. We demonstrate how LaMachine can create a fully functioning and standalone research environment for text mining and NLP for Dutch texts in a use case project at the Healthcare Inspectorate.

2 Architecture

Being an open-source NLP software distribution, LaMachine is constrained to Unix-like platforms; this primarily means Linux, but also BSD and, with some restrictions, macOS. Cygwin[4] is not tested or supported. This constraint stands in contrast with mobile platforms (Android/iOS/etc), native Windows/mac desktop software, or certain interface types in general such as classical desktop GUI applications, all of which fall beyond the scope of LaMachine. However, virtualisation technology enables deployment on a wider range of platforms, including Windows. All software that is incorporated in LaMachine must 1)

[1]Command line interfaces, programming interfaces, web-user interfaces, webservices.
[2]Data scientists, DevOps, system administrators, developers.
[3]The wider researcher community, particularly the Humanities; also educational settings.
[4]A unix environment on Windows

bear some relevance to NLP, 2) be under a recognised open-source license, 3) be deposited in a public version controlled repository[5] and 4) have a release protocol (with semantic versioning) using the proper technology-specific channels.

LaMachine is a *meta distribution* as it can be installed in various contexts. At its core, LaMachine consists of a set of machine-parsable instructions on how to obtain, build (e.g. compile from source), install and configure software. These are implemented using Ansible[6]. This is notably different from the more classical notion of Linux distributions, which generally provide their own repositories with (often binary) software packages. LaMachine builds on this already established infrastructure by taking these repositories as a given and only needs to know which repositories to use. Similarly, there are different programming-language-specific ecosystems providing their own repositories, such as the Python Package Index[7] for Python, CRAN[8] for R, CPAN[9] for Perl, Maven Central[10] for Java. LaMachine again relies on those to pull and install software from and never forks, archives, or modifies the software in any way. In doing so, we compel participating software projects to adhere to well-established distribution standards and ensure the software is more sustainable towards the future (van Gompel et al., 2016). Moreover, we ensure that LaMachine never becomes a prerequisite for the software but merely a courtesy or convenience.

LaMachine provides ample flexibility that allows it to be deployable in different contexts. First of all there is flexibility with regard to the target platform, where we support several major GNU/Linux distributions (Debian, Ubuntu, CentOS, RedHat Enterprise Linux, Fedora, Arch Linux), as well as macOS. Second, there is flexibility with regard to the form, where we support *containerisation* through Docker[11], *virtualisation* through Vagrant[12] and VirtualBox[13], direct remote provisioning through Ansible (for production servers), or an installation that is either global to the machine or local in a custom directory for a specific user. Pre-built docker containers and virtual machines with a limited selection of participating software are regularly uploaded to the Docker Hub and Vagrant Cloud, respectively.

LaMachine also aims to harmonise the metadata of all installed software, by converting metadata from upstream repositories[14] to the CodeMeta standard[15] (Jones et al., 2016; Boettiger, 2017) where possible, or encouraging software developers to provide their own. This in turn enables other tools to do proper service discovery and provenance logging.

3   Software

As LaMachine was conceived initially[16] as the primary means of distribution of the software stack developed at CLST, Radboud University Nijmegen, it includes a lot of our software. A full list goes beyond the scope of this overview; we will merely mention some CLARIN-NL/CLARIAH-funded tools: ucto (a tokeniser), Frog (an NLP suite for Dutch), FoLiA (Format for Linguistic Annotation, with assorted tools), FLAT (a web-based linguistic Annotation tool), PICCL (an OCR and post-OCR correction pipeline) and CLAM. We already include some relevant software by the University of Groningen and VU Amsterdam as well. Moreover, LaMachine incorporates a large number of renowned tools by external international parties, offering most notably a mature Python environment[17], but also R and Java.

4 Case study

We participated in the dutch ZonMw project entitled "Tekstmining in het toezicht: een exploratieve studie naar de automatische verwerking van klachten ingediend bij het Landelijk Meldpunt Zorg"[18] led by IQhealthcare[19], the scientific centre for healthcare quality of RadboudUMC. This project took place at the Dutch Health Inspectorate and aimed to apply text mining techniques to health care complaints that have been registered at the national contact point for health care (Landelijk Meldpunt Zorg `https://www.landelijkmeldpuntzorg.nl`) We investigated the usefulness of text mining to categorise and cluster complaints, to automatically determine the severity of incoming complaints, to extract patterns and to identify risk cases. This project turned out to be a good test case of the applicability and usefulness of LaMachine as a standalone research environment. As the complaint data is highly sensitive, it could not leave the secure servers from the health inspectorate and was stored an environment without internet access. We needed to bring the software to the data via a shared folder.

We used a virtual machine (VM) image of LaMachine. Installation of LaMachine always begins with a single bootstrap command[20] and we opted to build a VM and succeeded in running this 64-bits Linux-based VM inside another VM with Windows 2012 in which we did have administrative rights but no internet access, i.e. the VM that was offered to us for this project. In terms of hardware we ran on a machine with 8 cores and 32GB internal memory available. Lamachine provided a fully functional research environment and we ran all our experiments within LaMachine. We interacted with LaMachine both through the command line, which offers a standard shell and enables access to all lower-level tools and programming languages; and through the (offline) webbrowser to use the Jupyter Notebook environment[21], which offers a more graphical scripting environment for e.g. Python and R that has gained great popularity in the scientific community. Moreover, LaMachine also offers a portal website with access and overview of all locally installed tools, including web services and web applications.

LaMachine comes with some simple data sharing facilities that allowed us to access the sensitive complaint data via a single shared dataspace between host and the VM. (Note that extensive data search and management functions are deliberately beyond the scope of LaMachine, and left to more high-level tooling.)

We used many of the available tools in LaMachine within this project: Frog for linguistic annotation of the textual content of the complaints, Timbl and the scikit-learn Python package (Pedregosa et al., 2011) for classification, T-scan for feature creation and colibri-core for n-gram analysis.

5 Conclusion & Future work

The recent release of LaMachine v2, which constituted a full rewrite, has opened up LaMachine to outside contribution. Contributor documentation has been written, and at this stage, we greatly welcome external participants to join in. Use cases as the example in section 4 contribute to thorough testing and running of LaMachine in less ideal circumstances such as nested VM constructions and offline usage.

Aside from the incorporation of new relevant software, the main objectives for the future are to provide greater *interoperability* between the included tools through better *high-level interfaces* for the researcher. We see this as a bottom-up process and have now established a firm foundation to build upon. Note that such proposed interfaces, including the current portal application in LaMachine, are always considered separate independent software projects, which may be deployed by/in/for LaMachine, but also in other contexts. LaMachine remains 'just' a software distribution at heart.

Development of LaMachine presently takes place in the scope of the CLARIAH WP3 Virtual Research Environment (VRE) project[22], which has higher ambitions in accommodating the researcher and connectivity of data and services, and transcends also those of the CLARIN Language Resource Switch-

board (Zinn, 2016). An important part of our future focus will therefore be on interoperability with the higher-level tools emerging from the VRE efforts, but also with other parts of the CLARIN infrastructure; single-sign on authentication being a notable example here.
